Sample Activity 19 Question and Solution

To illustrate, here is a typical sample problem and detailed solution:

Question:

The demand function for a product is given by $Q_d = 100 - 2P$, where Q_d is the quantity demanded and P is the price. The supply function is $Q_s = 20 + 3P$.

- Find the equilibrium price and quantity.
- Calculate the price elasticity of demand at the equilibrium point.
- Determine the consumer surplus at equilibrium.

Solution:

Part a: Finding equilibrium price and quantity

Set $(Q_d = Q_s)$:

$\{$

$$100 - 2P = 20 + 3P$$

$\}$

$\{$

$$100 - 20 = 3P + 2P$$

$\}$

$\{$

$$80 = 5P$$

$\}$

$\{$

$$P_{eq} = \frac{80}{5} = 16$$

$\}$

Now, substitute (P_{eq}) back into either demand or supply function:

$\{$

$$Q_d = 100 - 2(16) = 100 - 32 = 68$$

$\}$

Equilibrium price: \$16

Equilibrium quantity: 68 units

Part b: Calculating price elasticity of demand at equilibrium

The price elasticity of demand (PED) is:

\[

$$PED = \frac{dQ_d}{dP} \times \frac{P}{Q_d}$$

\]

Given \((Q_d = 100 - 2P)\), the derivative:

\[

$$\frac{dQ_d}{dP} = -2$$

\]

At the equilibrium point:

\[

$$PED = -2 \times \frac{16}{68} \approx -2 \times 0.2353 \approx -0.4706$$

\]

The absolute value:

\[

$$|PED| \approx 0.471$$

\]

Since the absolute value is less than 1, demand is inelastic at equilibrium.

Part c: Consumer surplus calculation

Consumer surplus is the area of the triangle between the demand curve and the price line, up to the equilibrium quantity:

[

$$CS = \frac{1}{2} \times (\text{base}) \times (\text{height})$$

]

- The height is the difference between the maximum price consumers are willing to pay (intercept of demand at $(Q=0)$) and the equilibrium price.

Find the maximum price:

[

$$Q_d = 0 \rightarrow 0 = 100 - 2P \rightarrow P = 50$$

]

So, the maximum price consumers are willing to pay is \$50.

- The base is the equilibrium quantity: 68 units.

- The height:

[

$$50 - 16 = 34$$

]

Calculate consumer surplus:

[

$$CS = \frac{1}{2} \times 68 \times 34 = 34 \times 34 = 1156$$

]

Answer: Consumer surplus at equilibrium is \$1156.

Core Mathematical Concepts in Activity 19

The solutions to Activity 19 predominantly rely on several fundamental mathematical principles:

1. Algebraic Manipulation

Basic algebra is essential for rearranging equations, solving for unknown variables, and simplifying expressions. Proficiency in algebra allows for:

- Isolating variables
- Combining like terms
- Factoring expressions

2. Calculus ? Derivatives and Optimization

Calculus is central in economic analysis for:

- Identifying maximum profit or utility
- Finding equilibrium points where supply equals demand

4. Application of Limits and Continuity

In certain cases, especially when dealing with asymptotic behavior or undefined points, limits are used to analyze the behavior of functions.

Step-by-Step Breakdown of the Typical Solution to Activity 19

While the exact content of Activity 19 varies, a common problem involves finding the profit-maximizing output level for a firm, given its cost and revenue functions. Here is a detailed step-by-step approach that aligns with typical answers.

Step 1: Define the Functions

- Revenue function ($R(x)$): Usually given as the product of price per unit and quantity, e.g., $R(x) = p(x) \times x$
- Cost function ($C(x)$): Total cost function based on production levels
- Profit function ($\pi(x)$): $\pi(x) = R(x) - C(x)$

For example, suppose:

- Price function: $p(x) = a - bx$ (a linear demand curve)
- Cost function: $C(x) = c + dx$ (including fixed and variable costs)

Step 2: Derive the Profit Function

Express profit explicitly:

$$\pi(x) = (p(x) x) - C(x)$$

Substituting the functions:

$$\pi(x) = (a - bx) x - (c + dx)$$

Simplify:

$$\pi(x) = ax - bx^2 - c - dx$$

Step 3: Find Critical Points via Derivatives

Calculate the derivative of the profit function with respect to x:

$$\pi'(x) = d\pi/dx = a - 2bx - d$$

Set $\pi'(x) = 0$ to find critical points:

$$a - 2bx - d = 0$$

Solve for x:

$$x = (a - d) / (2b)$$

This is the candidate for the profit-maximizing output level.

Step 4: Verify the Nature of Critical Points

Calculate the second derivative:

$$\pi''(x) = d^2\pi/dx^2 = -2b$$

Since $b > 0$ (assuming typical demand slopes), $\pi''(x)$

Step 5: Confirm the Economic Validity of the Solution

- Check if x falls within feasible production limits (e.g., $x \geq 0$)
- Calculate the profit at x:

$$\pi(x) = a x - b x^2 - c - d x$$

- Compare with profit at boundaries (e.g., zero output) to ensure global maximum

Step 6: Interpret the Result

- The value of x indicates the optimal production quantity
- Corresponding maximum profit can be computed
- Economic implications: efficiency, market equilibrium, or competitive advantage

Common Mistakes and How to Avoid Them

Even experienced students can make errors when solving Activity 19. Awareness of common pitfalls enhances accuracy:

- Mismanaging algebraic expressions: Mistakes in expanding or simplifying functions lead to incorrect derivatives.
- Incorrect differentiation: Forgetting the product rule or chain rule when functions involve multiple variables.
- Ignoring domain restrictions: Not verifying whether the critical point is within feasible or realistic production levels.
- Forgetting to verify whether the critical point is a maximum or minimum: Always check the second derivative.
- Overlooking economic constraints: For example, negative production levels are not feasible; solutions must make sense economically.

Applying the Answer to Broader Economic Concepts

The solution to Activity 19 is more than a mathematical exercise; it encapsulates critical economic insights:

- Profit Maximization: Identifies the output level where marginal revenue equals marginal cost.
- Price Elasticity: The shape and slope of the demand curve influence the optimal output.
- Market Equilibrium: The solution may inform about where supply meets demand.
- Producer and Consumer Surplus: The optimal point affects overall welfare.

Understanding the detailed answer enhances the ability to interpret real-world economic data and

inform policy decisions.

In this article, we will explore the key concepts involved in Activity 21, provide step-by-step solutions, and offer valuable tips to master similar economic math problems.

Understanding the Context of Economics Activity 21

What Is Economics Activity 21?

Economics activities are designed to help learners apply theoretical concepts through practical problems. Activity 21 typically involves analyzing economic data, calculating economic indicators, or solving quantitative problems related to supply, demand, elasticity, or other economic variables.

Importance of Math in Economics

- Quantitative Analysis: Economics heavily relies on mathematical models to interpret data and forecast trends.
- Decision Making: Accurate calculations assist policymakers and businesses in making informed decisions.
- Understanding Relationships: Math helps illustrate relationships between variables, such as price and quantity.

Key Mathematical Concepts in Economics Activity 21

1. Marginal Analysis

Involves calculating marginal cost, marginal revenue, or marginal utility to determine optimal output or consumption levels.

2. Elasticity

Measures responsiveness of quantity demanded or supplied to changes in price or other factors.

3. Cost and Revenue Calculations

Includes total cost, total revenue, average cost, and profit calculations.

4. Break-Even Analysis

Determining the point where total revenue equals total cost, meaning no profit or loss.

Step-by-Step Solution to Math Practice for Economics Activity 21

Sample Problem Statement

Suppose a firm produces a product with the following data:

- Price per unit: \$50
- Quantity sold: 1000 units
- Total fixed costs: \$10,000
- Variable costs per unit: \$30

Calculate the following:

- Total revenue
- Total variable costs
- Total costs
- Profit or loss
- Break-even quantity

Solution Steps

1. Calculating Total Revenue (TR)

$TR = \text{Price per unit} \times \text{Quantity sold}$

$$TR = \$50 \times 1000 = \$50,000$$

2. Calculating Total Variable Costs (TVC)

$TVC = \text{Variable cost per unit} \times \text{Quantity sold}$

$$\text{TVC} = \$30 \times 1000 = \$30,000$$

3. Calculating Total Costs (TC)

Total costs include fixed and variable costs:

$$\text{TC} = \text{Fixed costs} + \text{Variable costs}$$

$$\text{TC} = \$10,000 + \$30,000 = \$40,000$$

4. Determining Profit or Loss

$$\text{Profit} = \text{Total Revenue} - \text{Total Costs}$$

$$\text{Profit} = \$50,000 - \$40,000 = \$10,000$$

Since the profit is positive, the firm is making a profit of \$10,000.

5. Calculating Break-Even Quantity

The break-even point occurs when Total Revenue equals Total Costs:

$$\text{Price per unit} \times \text{Break-even quantity} = \text{Fixed costs} + \text{Variable cost per unit} \times \text{Break-even quantity}$$

$$50Q = 10,000 + 30Q$$

$$50Q - 30Q = 10,000$$

$$20Q = 10,000$$

$$Q = 10,000 \div 20 = 500 \text{ units}$$

Thus, the firm breaks even at 500 units sold.

Math Practice for Economics Activity 21 Answer: A Comprehensive Guide for Students and Enthusiasts

In the world of economics, quantitative analysis plays a vital role in understanding market behaviors, making informed decisions, and developing strategic insights. For students and practitioners alike, mastering the mathematical components of economics activities is essential. One such activity that often challenges learners is "Economics Activity 21," which involves applying mathematical principles to economic scenarios. This article aims to provide a detailed, reader-friendly exploration of the solutions to this activity, focusing on the math practice involved and how to approach similar problems effectively.

Understanding the Context of Activity 21 in Economics

Before diving into the specifics of the answer, it's important to grasp the context in which Activity 21 is situated. Typically, such activities are designed to assess a student's ability to apply mathematical tools—like algebra, functions, graphs, and basic calculus—to economic concepts such as supply and demand, elasticity, cost analysis, and market equilibrium.

Key objectives of Activity 21 might include:

- Calculating equilibrium points in a market.
- Determining price elasticity of demand.
- Analyzing cost functions and profit maximization.
- Interpreting graphs to understand market dynamics.

By understanding the purpose behind the activity, students can better focus on the mathematical techniques required to find accurate solutions and develop a solid conceptual understanding.

Breaking Down the Mathematical Components of Activity 21

The core of Activity 21 involves several mathematical steps. Let's explore these components systematically.

- Formulating the Economic Equations

Most economic problems revolve around defining functions that describe economic relationships. For example:

- Demand Function: $(Q_d = a - bP)$
- Supply Function: $(Q_s = c + dP)$

Where:

- (Q_d) and (Q_s) are quantities demanded and supplied.
- (P) is the price.
- (a, b, c, d) are constants derived from data.

Example: Suppose the demand function is $(Q_d = 100 - 2P)$, and the supply function is $(Q_s = 20 + 3P)$.

- Finding the Equilibrium Price and Quantity

The equilibrium occurs where quantity demanded equals quantity supplied:

$$Q_d = Q_s$$

Using the example:

$$100 - 2P = 20 + 3P$$

Solving for (P) :

$$100 - 20 = 3P + 2P$$

$$80 = 5P$$

$$P = \frac{80}{5} = 16$$

Plug back into either function to find the equilibrium quantity:

$$Q_d = 100 - 2(16) = 100 - 32 = 68$$

Thus, the equilibrium price is \$16, and the equilibrium quantity is 68 units.

- Calculating Price Elasticity of Demand

Price elasticity measures how much quantity demanded responds to price changes:

$$E_d = \frac{\% \text{ change in quantity demanded}}{\% \text{ change in price}}$$

Mathematically:

$$E_d = \frac{dQ_d}{dP} \times \frac{P}{Q_d}$$

For the demand function $(Q_d = 100 - 2P)$:

$$\left(\frac{dQ_d}{dP} = -2 \right)$$

Using the equilibrium values:

$$E_d = -2 \times \frac{16}{68} \approx -2 \times 0.235 = -0.47$$

The absolute value indicates demand is inelastic at this price point (since $|E_d|$

- Profit and Cost Analysis

Suppose a firm's total cost function is:

$$TC = 50 + 4Q$$

and the market price is $(P = 16)$. The profit:

$$\pi = (P \times Q) - TC$$

At equilibrium $(Q = 68)$:

$$\pi = (16 \times 68) - (50 + 4 \times 68)$$

$$= 1088 - (50 + 272)$$

$$= 1088 - 322 = 766$$

The firm's profit at this point is \$766.

Problem 1: Calculating Marginal Revenue

Suppose the total revenue function for a firm is given by $TR(q) = 50q - 2q^2$, where q is the quantity sold.

Question: Find the marginal revenue when $q = 10$.

Solution:

- Recall that marginal revenue (MR) is the derivative of total revenue:

$$MR(q) = d(TR)/dq = 50 - 4q$$

- Substitute $q = 10$:

$$MR(10) = 50 - 4(10) = 50 - 40 = 10$$

Answer: The marginal revenue at $q = 10$ is 10.

Problem 2: Determining Profit-Maximizing Output

Given the cost function $C(q) = 20 + 3q$ and the revenue function $R(q) = 50q - q^2$, find the quantity q that maximizes profit.

Solution:

- Write the profit function:

$$\pi(q) = R(q) - C(q) = (50q - q^2) - (20 + 3q) = 50q - q^2 - 20 - 3q = (50q - 3q) - q^2 - 20 = 47q - q^2 - 20$$

- Find the derivative of $\pi(q)$:

$$d\pi/dq = 47 - 2q$$

- Set the derivative to zero to find critical points:

$$47 - 2q = 0 \Rightarrow 2q = 47 \Rightarrow q = 23.5$$

- Confirm maximum by the second derivative:

$$d^2\pi/dq^2 = -2$$

Answer: The profit is maximized when $q = 23.5$ units.

Students practice deriving equilibrium prices by solving equations where quantity demanded equals quantity supplied. Graphical analysis complements algebraic solutions, illustrating how shifts in curves affect market equilibrium.

Key skills developed:

- Setting up demand and supply equations
- Solving systems of equations
- Interpreting shifts and their impact on equilibrium

Cost and Revenue Optimization

Using calculus, students analyze cost functions to identify profit-maximizing output levels. This involves calculating derivatives and setting them to zero to find critical points.

Example exercise:

- Given a total cost function $C(q)$ and total revenue function $R(q)$, find the quantity q that maximizes profit $\pi(q) = R(q) - C(q)$.

Economic Forecasting and Risk Assessment

Probability exercises help students understand the likelihood of economic events, such as inflation rates or unemployment trends. Statistical analysis enables better forecasting and risk management.

Practical skills include:

- Computing expected values
- Interpreting confidence intervals
- Conducting hypothesis tests on economic data
