Signal Conditioning Circuit

Raw signals from sensors are often weak or distorted. Signal conditioning involves processes such as amplification, filtering, isolation, and conversion to prepare the signal for further processing. This stage enhances signal quality and ensures compatibility with subsequent components.

Amplifier

Amplifiers increase the magnitude of the conditioned signal to levels suitable for processing and analysis. This step is critical when dealing with low-level signals from sensors.

Analog-to-Digital Converter (ADC)

Most modern systems process digital signals. The ADC converts the analog voltage or current signals into digital data that can be processed by microcontrollers or digital systems.

Processing Unit (Controller or Data Processor)

This component interprets the digital data, performs calculations, controls outputs, or triggers alarms. It often includes microcontrollers, microprocessors, or digital signal processors (DSPs).

Display and Output Devices

Processed data is presented to users through displays, gauges, or interfaces. Additionally, control signals can be sent to actuators, valves, or motors to effect changes in the controlled environment.

Feedback Loop (if applicable)

In control systems, a feedback loop is incorporated to compare the measured parameter with a desired setpoint, enabling automatic adjustments and maintaining stability.
